Lecture 9: AVL Trees

Heading: AVL Trees
An AVL Tree is a self-balancing binary search tree. For every node in an AVL tree, the heights of the left and right subtrees differ by at most one. This height difference is termed the balance factor.

When an insertion or deletion causes a node balance factor to violate the invariant (-1, 0, or 1), tree rotations (left rotation, right rotation, left-right rotation, right-left rotation) restore balance while preserving the binary search tree ordering.
